Series 1 Vector Differentiation and Applications

Series Outline

- **Part 1.1: Fundamentals of Vectors in Analysis**
 - Definition and representation of vectors
 - Vector operations: addition, scalar multiplication, dot and cross products
- **Part 1.2: Vector Differentiation**
 - Concept of vector functions
 - Differentiation of vector functions
 - Higher-order derivatives of vector functions
- **Part 1.3: Applications of Vector Differentiation**
 - Velocity and acceleration in vector form
 - Tangent and normal vectors
 - Curvature and torsion
- **Part 1.4: Vector Integration and Applications**
 - Integration of vector functions
 - Physical applications: displacement, work, and circulation

Introduction

Vectors are fundamental tools in mathematics and physics, providing a way to represent quantities that have both magnitude and direction. From describing the motion of particles to analysing forces in engineering, vectors allow us to capture real-world phenomena in a precise mathematical form. In this Series, we focus on how vectors can be differentiated and integrated, and how these operations lead to powerful applications in science and technology.

The aim of this Series is to equip you with the knowledge and skills to perform vector differentiation and integration, and to apply these techniques in solving practical problems involving motion, geometry, and physical quantities.

We shall commence this Series by exploring the fundamentals of vectors in analysis, including their representation and basic operations. Next, we will move on to vector differentiation, where we will examine how vector functions can be differentiated and extended to higher-order derivatives. Following that, we will study applications of vector differentiation, such as velocity, acceleration, tangent and normal vectors, and curvature. Finally, we will conclude with vector integration and its applications, including displacement, work, and circulation, thereby rounding off the Series with a strong link to physical interpretations.

Series Learning Outcomes

Upon completing this Series, you should be able to:

- SLO 1.1 define vectors and explain their representation and basic operations in analysis,
- SLO 1.2 demonstrate how to differentiate vector functions, including higher-order derivatives,
- SLO 1.3 apply vector differentiation to problems involving velocity, acceleration, tangent and normal vectors, and curvature,
- SLO 1.4 perform vector integration and evaluate its applications in displacement, work, and circulation.

1.1 Fundamentals of Vectors in Analysis

Vectors are central to mathematics and physics because they represent quantities that have both magnitude (size) and direction. A vector is defined as an ordered pair or tuple of numbers that indicate position or displacement in space. For example, in two dimensions, a vector can be written as y , while in three dimensions it is expressed as z . Vectors are often represented graphically as arrows, where the length of the arrow corresponds to the magnitude and the orientation corresponds to the direction.

Fill in the blank: A vector is defined as a quantity that has both _____ and _____.

1.1.1 Representation of vectors

Vectors can be represented in different forms. The most common are:

- Geometric representation: An arrow drawn in space, starting at one point and ending at another.
- Algebraic representation: A tuple of numbers, such as $\mathbf{z}$, that specifies the components of the vector.
- Unit vector representation: A vector expressed in terms of unit vectors along coordinate axes, such as $\mathbf{v} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$.

Vector Representation: Geometric & Algebraic Forms

2D Space

Geometric: Arrow from origin

Algebraic: $\mathbf{v} = (3, 2)$ or $\mathbf{v} = 3\mathbf{i} + 2\mathbf{j}$

3D Space

Geometric: Arrow from origin

Algebraic: $\mathbf{v} = (4, 3, 5)$ or $\mathbf{v} = 4\mathbf{i} + 3\mathbf{j} + 5\mathbf{k}$

Geometric and algebraic representation of vectors

Fill in the blank: A vector expressed as $x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$ is written in _____ vector form.

1.1.2 Vector operations

Vectors can be manipulated using several operations:

- **Addition:** The sum of two vectors is obtained by adding their corresponding components.
- **Scalar multiplication:** Multiplying a vector by a scalar changes its magnitude but not its direction (unless the scalar is negative, which reverses the direction).
- **Dot product:** The dot product of two vectors is a scalar defined as $\mathbf{a} \cdot \mathbf{b} = |\mathbf{a}||\mathbf{b}|\cos\theta$, where θ is the angle between them.
- **Cross product:** The cross product of two vectors is another vector defined as $\mathbf{a} \times \mathbf{b} = |\mathbf{a}||\mathbf{b}|\sin\theta \mathbf{n}$, where $\mathbf{n}$ is a unit vector perpendicular to both $\mathbf{a}$ and $\mathbf{b}$.

Table comparing addition, scalar multiplication, dot product, and cross product.

Summary of Vector Operations

Operation	Algebraic Formula (for $\mathbf{u}, \mathbf{v} \in \mathbb{R}^3$)	Result Type	Geometric Meaning / Use
Addition	$(u_1 + v_1, u_2 + v_2, u_3 + v_3)$	Vector	Tip-to-Tail: The combined effect of two displacements.
Scalar Multiplication	(cu_1, cu_2, cu_3)	Vector	Scaling: Changes length and/or reverses direction ($c < 0$).
Dot Product	$u_1v_1 + u_2v_2 + u_3v_3$	Scalar	Projection: Measures how much one vector goes in the direction of another. $\mathbf{u} \cdot \mathbf{v} = 0$ means they are orthogonal .
Cross Product	$(u_2v_3 - u_3v_2, u_3v_1 - u_1v_3, u_1v_2 - u_2v_1)$	Vector	Orthogonality: Produces a vector perpendicular to the plane of $\mathbf{u}$ and $\mathbf{v}$.

Fill in the blank: The dot product of two vectors results in a _____, while the cross product results in a _____.

1.1.3 Applications of vectors in analysis

Vectors are widely applied in analysis and physical sciences. They are used to describe displacement, velocity, acceleration, and forces. For example, in physics, the motion of a particle can be described by a position vector, and its rate of change gives velocity. Similarly, vectors are used in geometry to define lines, planes, and directions.

Box summarising applications of vectors in describing motion, forces, and geometric objects.

Applications of Vectors

In Physics

- **Kinematics:** Representing **Displacement**, **Velocity**, and **Acceleration**. A car moving north at 60 mph is a vector; without the direction, it's just speed.
- **Dynamics: Force** is a vector ($F = ma$). The Net Force is found using vector addition to see if an object will move or stay in equilibrium.
- **Work and Energy:** The **Dot Product** calculates Work ($W = F \cdot d$), showing that only the force applied in the direction of movement does work.
- **Rotational Motion:** The **Cross Product** defines **Torque** ($\tau = r \times F$) and Angular Momentum, determining how forces cause objects to rotate.
- **Electromagnetism:** Electric and Magnetic fields are described as **Vector Fields**, where every point in space has a magnitude and direction of force.

In Geometry

- **Defining Lines and Planes:** In 3D space, lines are defined by a point and a direction vector; planes are defined by a point and a **Normal Vector** (perpendicular to the surface).
- **Distance Calculations:** Using projections (dot products) to find the shortest distance between a point and a line or between two skewed lines.
- **Area and Volume:** The magnitude of a cross product $\|u \times v\|$ gives the area of a parallelogram, while the **Scalar Triple Product** $a \cdot (b \times c)$ gives the volume of a parallelepiped.
- **Computer Graphics:** Vectors handle everything from 3D modeling to "Ray Tracing," calculating how light bounces off surfaces based on the surface normal vector.

Mathematical Tool	Physical Equivalent
Vector Addition	Resultant Force / Relative Velocity
Dot Product	Work Done / Flux
Cross Product	Torque / Magnetic Force ($qv \times B$)
Unit Vector	Direction of travel (Heading)

Fill in the blank: In physics, the motion of a particle is described by its _____ vector.

Pilot questions 1.1

1. A vector is defined as a quantity that has: A. Magnitude only B. Direction only C. Magnitude and direction D. None of the above (Linked to SLO 1.1)
2. A vector expressed as $xi+yj+zk$ is written in: A. Geometric form B. Algebraic form C. Unit vector form D. None of the above (Linked to SLO 1.1)
3. The dot product of two vectors results in: A. A vector B. A scalar C. A matrix D. None of the above (Linked to SLO 1.1)
4. The cross product of two vectors results in: A. A scalar B. A vector C. A number D. None of the above (Linked to SLO 1.1)
5. In physics, the motion of a particle is described by its: A. Force vector B. Position vector C. Acceleration vector D. None of the above (Linked to SLO 1.1)

1.2 Vector Differentiation

Vector differentiation is the process of finding the derivative of a vector function, which is a function whose output is a vector rather than a scalar. A vector function can be written as $r(t)=x(t)i+y(t)j+z(t)k$, where $x(t),y(t),z(t)$ are scalar functions of a variable t . Differentiating such a function involves differentiating each component separately.

Fill in the blank: A vector function can be written as $r(t)=x(t)i+y(t)j+z(t)k$, where _____ are scalar functions of t .

1.2.1 Differentiation of vector functions

The derivative of a vector function $r(t)$ with respect to t is given by:

$$dr(t)dt=dx(t)dti+dy(t)dtj+dz(t)dtk$$

This derivative represents the rate of change of the vector function with respect to the variable. In physical terms, if $r(t)$ represents the position of a particle, then $dr(t)dt$ represents its velocity.

Particle Motion & Vector Differentiation

Position, Velocity, and Tangency

The velocity vector $v(t)$ is the derivative of the position vector $r(t)$ with respect to time (t). It is always tangent to the particle's path.

$$v(t) = \frac{dr(t)}{dt}$$

Differentiation of a vector function representing motion along a curve

Fill in the blank: If $\mathbf{r}(t)$ represents the position of a particle, then $\frac{d\mathbf{r}(t)}{dt}$ represents its _____.

1.2.2 Higher-order derivatives of vector functions

Just as with scalar functions, vector functions can be differentiated multiple times. The second derivative of the position vector $\mathbf{r}(t)$ is:

$$\frac{d^2\mathbf{r}(t)}{dt^2} = \frac{d^2x(t)}{dt^2}\mathbf{i} + \frac{d^2y(t)}{dt^2}\mathbf{j} + \frac{d^2z(t)}{dt^2}\mathbf{k}$$

This second derivative represents the acceleration vector of the particle. Higher-order derivatives can also be defined, though in most physical applications, the first and second derivatives are the most important.

Box summarising velocity as the first derivative and acceleration as the second derivative of position vector

Motion Derivatives of a Position Vector

1. Position Vector: $\mathbf{r}(t)$

Represents the location of a particle at time t . In 3D space, it is defined as:

$$\mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$$

2. Velocity Vector: $\mathbf{v}(t)$

The **first derivative** of position with respect to time. It represents the instantaneous rate of change of position and is always **tangent** to the path of motion.

$$\mathbf{v}(t) = \frac{d\mathbf{r}}{dt} = x'(t)\mathbf{i} + y'(t)\mathbf{j} + z'(t)\mathbf{k}$$

- **Speed:** The magnitude of the velocity vector, $\|\mathbf{v}(t)\|$.

3. Acceleration Vector: $\mathbf{a}(t)$

The **second derivative** of position (or the first derivative of velocity). It represents how the velocity is changing in both magnitude and direction.

$$\mathbf{a}(t) = \frac{d\mathbf{v}}{dt} = \frac{d^2\mathbf{r}}{dt^2} = x''(t)\mathbf{i} + y''(t)\mathbf{j} + z''(t)\mathbf{k}$$

Key Calculus Rules for Vectors

Since vector differentiation is performed component-wise, many standard rules apply:

- **Sum Rule:** $\frac{d}{dt}[\mathbf{u}(t) + \mathbf{v}(t)] = \mathbf{u}'(t) + \mathbf{v}'(t)$
- **Product Rule (Scalar):** $\frac{d}{dt}[f(t)\mathbf{u}(t)] = f'(t)\mathbf{u}(t) + f(t)\mathbf{u}'(t)$
- **Dot Product Rule:** $\frac{d}{dt}[\mathbf{u}(t) \cdot \mathbf{v}(t)] = \mathbf{u}'(t) \cdot \mathbf{v}(t) + \mathbf{u}(t) \cdot \mathbf{v}'(t)$
- **Cross Product Rule:** $\frac{d}{dt}[\mathbf{u}(t) \times \mathbf{v}(t)] = \mathbf{u}'(t) \times \mathbf{v}(t) + \mathbf{u}(t) \times \mathbf{v}'(t)$

Interpreting the Geometry

- If $\|\mathbf{v}(t)\|$ is constant, the acceleration $\mathbf{a}(t)$ is always **orthogonal** (perpendicular) to the velocity $\mathbf{v}(t)$. This is common in uniform circular motion.
- The velocity vector provides the direction of travel, while the acceleration vector points toward the "inside" of the curve the particle is following.

Fill in the blank: The second derivative of the position vector represents the particle's _____.

Pilot questions 1.2

1. A vector function can be written as: A. A scalar function of t B. A tuple of scalar functions of t C. A constant vector D. None of the above (Linked to SLO 1.2)

2. The derivative of a vector function is obtained by: A. Differentiating the magnitude only B. Differentiating each component separately C. Differentiating the direction only D. None of the above (Linked to SLO 1.2)
3. If $\mathbf{r}(t)$ represents position, then $d\mathbf{r}(t)/dt$ represents: A. Force B. Velocity C. Acceleration D. None of the above (Linked to SLO 1.2)
4. The second derivative of the position vector represents: A. Velocity B. Acceleration C. Displacement D. None of the above (Linked to SLO 1.2)
5. Higher-order derivatives of vector functions are: A. Not possible B. Possible and useful in physical applications C. Only defined for scalars D. None of the above (Linked to SLO 1.2)

1.3 Applications of Vector Differentiation

Vector differentiation is not only a mathematical procedure but also a powerful tool for interpreting physical phenomena. When a vector function represents the position of a particle, its derivatives provide meaningful quantities such as velocity, acceleration, and geometric descriptors like tangent vectors, normal vectors, and curvature. These applications allow us to connect abstract mathematics with real-world motion and geometry.

Fill in the blank: The derivative of a position vector with respect to time gives the particle's _____.

1.3.1 Velocity and acceleration in vector form

If $\mathbf{r}(t)$ is the position vector of a particle, then:

- The velocity vector is $\mathbf{v}(t) = d\mathbf{r}(t)/dt$, which indicates the rate of change of position.
- The acceleration vector is $\mathbf{a}(t) = d^2\mathbf{r}(t)/dt^2$, which indicates the rate of change of velocity.

These vectors are essential in mechanics, as they describe how an object moves and how its motion changes over time.

Particle Trajectory & Vector Derivatives

Position, Velocity, and Acceleration

The velocity vector $v(t)$ is tangent to the path.
The acceleration vector $a(t)$ shows how velocity is changing, pointing towards the curve's center.

Velocity and acceleration vectors along a trajectory

Fill in the blank: The acceleration vector is the derivative of the _____ vector.

1.3.2 Tangent and normal vectors

The tangent vector to a curve at a point is given by the velocity vector, as it points in the direction of motion. The normal vector is perpendicular to the tangent and points towards the centre of curvature of the path. Together, these vectors describe the orientation of a particle's motion along a curve.

Frenet-Serret Frame: Tangent & Normal Vectors

Analyzing a Curve's Direction & Curvature.

The unit tangent vector $\mathbf{T}(t)$ is tangent to the curve, showing direction. The principal unit normal vector $\mathbf{N}(t)$ is perpendicular to $\mathbf{T}(t)$, pointing towards the center of curvature.

Tangent and normal vectors along a curve

Fill in the blank: The tangent vector to a curve at a point is given by the _____ vector.

1.3.3 Curvature and torsion

The curvature of a curve measures how sharply it bends at a point. It is defined as the rate of change of the tangent vector with respect to arc length. The torsion of a curve measures how much the curve twists out of the plane of curvature. These

quantities are important in geometry and physics, especially in describing the motion of particles along complex paths.

Box summarising curvature as bending of a curve and torsion as twisting out of plane.

Comparison Table

Feature	Curvature (κ)	Torsion (τ)
Geometric Meaning	"Bending"	"Twisting"
Failure to be Zero	If $\kappa \neq 0$, it's not a line.	If $\tau \neq 0$, it's not planar.
Relates to...	The Normal vector N	The Binormal vector B

Fill in the blank: Curvature measures how sharply a curve _____ at a point.

Pilot questions 1.3

1. The derivative of the position vector with respect to time gives: A. Force B. Velocity C. Acceleration D. None of the above (Linked to SLO 1.3)
2. The acceleration vector is the derivative of the: A. Position vector B. Velocity vector C. Tangent vector D. None of the above (Linked to SLO 1.3)
3. The tangent vector to a curve at a point is given by the: A. Position vector B. Velocity vector C. Acceleration vector D. None of the above (Linked to SLO 1.3)
4. Curvature measures: A. How sharply a curve bends B. How fast a particle moves C. How much a curve twists out of plane D. None of the above (Linked to SLO 1.3)
5. Torsion measures: A. Bending of a curve B. Twisting of a curve out of plane C. Rate of change of velocity D. None of the above (Linked to SLO 1.3)

1.4 Vector Integration and Applications

Vector integration is the process of integrating vector functions, which are functions that return vectors as outputs. Just as differentiation of vector functions gives velocity and acceleration, integration allows us to calculate quantities such as displacement, work, and circulation. A vector integral is obtained by integrating each component of the vector function separately.

Fill in the blank: A vector integral is obtained by integrating each _____ of the vector function separately.

1.4.1 Integration of vector functions

If $\mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j} + z(t)\mathbf{k}$, then its integral with respect to t is:

$$\int \mathbf{r}(t) dt = \int x(t) dt \mathbf{i} + \int y(t) dt \mathbf{j} + \int z(t) dt \mathbf{k}$$

This integral represents the accumulation of the vector function over time or another variable.

Vector Function Integration

Integrating Component-Wise

The integral of a vector function is found by integrating each component function separately:

$$\int_b^a \mathbf{r}(t) dt = \left(\int_b^a x(t) dt \right) \mathbf{i} + \left(\int_b^a y(t) dt \right) \mathbf{j} + \left(\int_b^a z(t) dt \right) \mathbf{k}$$

Integration of a vector function by components

Fill in the blank: The integral of a vector function is obtained by integrating each of its _____ separately.

1.4.2 Displacement and work

- Displacement: If velocity is given as a vector function $\mathbf{v}(t)$, then displacement is obtained by integrating velocity:

$$\mathbf{r}(t) = \int \mathbf{v}(t) dt$$

- Work: Work done by a force $\mathbf{F}$ along a path is given by the line integral:

$$W = \int_C \mathbf{F} \cdot d\mathbf{r}$$

This integral calculates the energy transferred when a force acts along a displacement.

Work as a Line Integral

Force, Displacement, and the Path

$$\text{Work} = \int_C \mathbf{F} \cdot d\mathbf{r}$$

This integral sums the force component along the direction of motion.

Work as a line integral of force along displacement

Fill in the blank: Work done by a force along a path is given by the _____ integral of force with displacement.

1.4.3 Circulation and physical applications

Circulation refers to the line integral of a vector field around a closed curve. It measures the tendency of the field to circulate around the curve. In fluid dynamics, circulation describes the rotation of fluid around a closed path. In electromagnetism, it is used to describe the behaviour of magnetic and electric fields.

Box summarising displacement, work, and circulation as applications of vector integration.

Application	Field Type	Path Type	Physical Significance
Displacement	Velocity	Open or Closed	Change in position.
Work	Force	Open or Closed	Energy transfer.
Circulation	Velocity (Fluid)	Closed Loop	Measure of rotation/vorticity.
Flow/Flux	Velocity	Across a Surface	Volume of fluid passing through a boundary.

Fill in the blank: Circulation is the line integral of a vector field around a _____ curve.

Pilot questions 1.4

1. A vector integral is obtained by: A. Differentiating each component B. Integrating each component separately C. Multiplying each component D. None of the above (Linked to SLO 1.4)
2. Displacement is obtained by integrating: A. Position B. Velocity C. Acceleration D. None of the above (Linked to SLO 1.4)
3. Work done by a force along a path is given by: A. A dot product B. A line integral C. A cross product D. None of the above (Linked to SLO 1.4)

4. Circulation measures: A. The tendency of a vector field to circulate around a closed curve B. The magnitude of a vector field C. The divergence of a vector field D. None of the above (Linked to SLO 1.4)
5. In fluid dynamics, circulation describes: A. The bending of a curve B. The rotation of fluid around a closed path C. The displacement of a particle D. None of the above (Linked to SLO 1.4)

Series Summary

This Series has introduced you to the foundations of vector differentiation and integration, highlighting their importance in both mathematics and physical applications. We began by examining the fundamentals of vectors, including their representation and basic operations, before moving on to the differentiation of vector functions and their higher-order derivatives. We then explored how these derivatives translate into meaningful physical quantities such as velocity, acceleration, tangent and normal vectors, and curvature. Finally, we concluded with vector integration, showing how it is applied to displacement, work, and circulation.

By completing this Series, you should now be able to define vectors and explain their representation and operations (SLO 1.1), demonstrate how to differentiate vector functions including higher-order derivatives (SLO 1.2), apply vector differentiation to problems involving motion and geometry (SLO 1.3), and perform vector integration with applications in displacement, work, and circulation (SLO 1.4). These outcomes provide a strong foundation for the subsequent Series, where we will build on these skills to study gradient, divergence, and curl.

Glossary of Terms

- Acceleration vector: The second derivative of the position vector with respect to time, representing the rate of change of velocity.
- Cross product: An operation between two vectors that produces another vector perpendicular to both, with magnitude equal to the product of their magnitudes and the sine of the angle between them.
- Curvature: A measure of how sharply a curve bends at a point, defined as the rate of change of the tangent vector with respect to arc length.
- Displacement: The change in position of a particle, obtained by integrating the velocity vector over time.

- Dot product: An operation between two vectors that produces a scalar equal to the product of their magnitudes and the cosine of the angle between them.
- Magnitude: The length or size of a vector, often represented by the norm of the vector.
- Normal vector: A vector perpendicular to the tangent vector at a point on a curve, pointing towards the centre of curvature.
- Position vector: A vector that specifies the location of a point or particle in space relative to an origin.
- Scalar multiplication: An operation where a vector is multiplied by a scalar, changing its magnitude but not its direction unless the scalar is negative.
- Tangent vector: A vector that points in the direction of motion along a curve, given by the velocity vector.
- Tensor: A mathematical object that generalises scalars, vectors, and matrices, used to describe relationships between sets of geometric quantities.
- Torsion: A measure of how much a curve twists out of the plane of curvature.
- Vector: A quantity that has both magnitude and direction, represented algebraically by components or geometrically by an arrow.
- Vector differentiation: The process of finding the derivative of a vector function by differentiating each component separately.
- Vector integration: The process of integrating a vector function by integrating each component separately.
- Velocity vector: The first derivative of the position vector with respect to time, representing the rate of change of position.

Concept Check Questions 1

Objective questions

1. A vector is defined as a quantity that has: A. Magnitude only B. Direction only C. Magnitude and direction D. None of the above (Linked to SLO 1.1)
2. The derivative of a vector function is obtained by: A. Differentiating the magnitude only B. Differentiating each component separately C. Differentiating the direction only D. None of the above (Linked to SLO 1.2)

3. The tangent vector to a curve at a point is given by the: A. Position vector B. Velocity vector C. Acceleration vector D. None of the above (Linked to SLO 1.3)
4. Work done by a force along a path is given by: A. A dot product B. A line integral C. A cross product D. None of the above (Linked to SLO 1.4)

Short-answer questions

5. Define a vector and give one example. (Linked to SLO 1.1)
6. Explain how to differentiate a vector function. (Linked to SLO 1.2)
7. State the physical meaning of the second derivative of a position vector. (Linked to SLO 1.2)
8. Describe the difference between tangent and normal vectors. (Linked to SLO 1.3)
9. What is circulation in vector integration? (Linked to SLO 1.4)

Long-answer questions

10. Discuss the representation and operations of vectors in analysis. (Linked to SLO 1.1)
 - Basic response: Define vectors, explain geometric and algebraic representation, and describe addition, scalar multiplication, dot product, and cross product.
 - Value-added response: Provide examples in two and three dimensions, and explain how these operations are applied in physics and geometry.
11. Analyse the role of vector differentiation in describing motion. (Linked to SLO 1.2, 1.3)
 - Basic response: Explain velocity and acceleration as derivatives of position.
 - Value-added response: Extend to tangent and normal vectors, curvature, and torsion, showing how they describe particle motion along curves.
12. Evaluate the applications of vector integration in physical sciences. (Linked to SLO 1.4)
 - Basic response: Define displacement, work, and circulation as outcomes of vector integration.

- Value-added response: Provide examples from mechanics, fluid dynamics, and electromagnetism, showing how vector integration links mathematics to physical phenomena.

Answers to Concept Check Questions 1

1. C
2. B
3. B
4. B
5. A vector is a quantity with magnitude and direction, e.g. displacement vector
6. Differentiate each component of the vector function separately.
7. The second derivative of position represents acceleration.
8. The tangent vector points along the curve, while the normal vector is perpendicular and points towards the centre of curvature.
9. Circulation is the line integral of a vector field around a closed curve.
10. Basic response: Vectors are represented geometrically as arrows and algebraically as components. Operations include addition, scalar multiplication, dot product, and cross product. Value-added response: In 2D, y represents displacement; in 3D, z represents position. Dot product is used for projections, cross product for perpendicular vectors in physics.
11. Basic response: Velocity is the first derivative of position, acceleration is the second derivative. Value-added response: Tangent vectors describe direction of motion, normal vectors describe curvature, and torsion describes twisting of the path.
12. Basic response: Displacement is integral of velocity, work is line integral of force, circulation is line integral of a field around a closed curve. Value-added response: In mechanics, work is energy transfer; in fluid dynamics, circulation measures rotation; in electromagnetism, it describes field behaviour.

Answers to Pilot Questions 1

Part 1.1: 1-C, 2-C, 3-B, 4-B, 5-B Part 1.2: 1-B, 2-B, 3-B, 4-B, 5-B Part 1.3: 1-B, 2-B, 3-B, 4-A, 5-B Part 1.4: 1-B, 2-B, 3-B, 4-A, 5-B

Series 2 Gradient, Divergence, and Curl

Series Outline

- **Part 2.1: Gradient of Scalar Fields**
 - Definition and interpretation of gradient
 - Properties of gradient
 - Applications in physical sciences
- **Part 2.2: Divergence of Vector Fields**
 - Definition and interpretation of divergence
 - Properties of divergence
 - Applications in fluid flow and electromagnetism
- **Part 2.3: Curl of Vector Fields**
 - Definition and interpretation of curl
 - Properties of curl
 - Applications in rotation and circulation
- **Part 2.4: Interrelationships of Gradient, Divergence, and Curl**
 - Vector identities involving gradient, divergence, and curl
 - Physical significance of these relationships
 - Examples in applied contexts

Introduction

Vectors can be extended beyond simple quantities to describe how scalar and vector fields change in space. In mathematics and physics, three important operators—**gradient**, **divergence**, and **curl**—allow us to capture these changes precisely. These concepts are fundamental in areas such as fluid dynamics, electromagnetism, and engineering, where they describe flow, rotation, and variation of fields. This Series will help you build a strong understanding of these operators and their applications.

The aim of this Series is to enable you to define, explain, and apply gradient, divergence, and curl, and to analyse their interrelationships in both mathematical and physical contexts.

We shall commence this Series by studying the gradient of scalar fields, focusing on its definition, properties, and applications. Next, we will move on to divergence of vector fields, examining how it measures the spreading out of a field and its relevance in physical sciences. Following that, we will explore curl of vector fields, which captures the rotational tendency of a field. Finally, we will conclude with the interrelationships among gradient, divergence, and curl, highlighting vector identities and their physical significance.

Series Learning Outcomes

Upon completing this Series, you should be able to:

- **SLO 2.1** define and explain the gradient of scalar fields, including its properties and applications,
- **SLO 2.2** demonstrate how to compute the divergence of vector fields and interpret its physical meaning,
- **SLO 2.3** apply the concept of curl to vector fields and analyse its role in describing rotation and circulation,
- **SLO 2.4** evaluate the interrelationships among gradient, divergence, and curl through vector identities and physical examples.

2.1 Gradient of Scalar Fields

The **gradient** is a vector operator that acts on a scalar field. A **scalar field** is a function that assigns a single value to every point in space, such as temperature or pressure. The gradient of a scalar field points in the direction of the greatest rate of increase of the field, and its magnitude represents how steeply the field changes.

Fill in the blank: The gradient of a scalar field points in the direction of the greatest rate of _____ of the field.

2.1.1 Definition and interpretation of gradient

If $\phi(x,y,z)$ is a scalar field, then its gradient is defined as:

$$\nabla\phi = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$$

This vector points in the direction of maximum increase of ϕ . For example, if ϕ represents temperature in a room, the gradient indicates the direction in which the temperature rises most rapidly.

Gradient of a scalar field indicating maximum rate of increase

Fill in the blank: The gradient of a scalar field is defined as $\nabla\phi = x\mathbf{i} + y\mathbf{j} + z\mathbf{k}$.

2.1.2 Properties of gradient

The gradient has several important properties:

- It is a vector quantity.
- It points in the direction of maximum increase of the scalar field.
- Its magnitude gives the rate of change in that direction.
- If the gradient is zero, the scalar field is constant in that region.

Properties of the gradient Short description: Box summarising the main properties of the gradient.

Fill in the blank: If the gradient of a scalar field is zero, the field is _____ in that region.

2.1.3 Applications in physical sciences

The gradient is widely used in physical sciences:

- In **heat transfer**, the gradient of temperature indicates the direction of heat flow.
- In **electrostatics**, the gradient of electric potential gives the electric field.
- In **geography**, the gradient of elevation represents the slope of terrain.

Gradient of temperature field showing heat flow direction

Fill in the blank: In electrostatics, the gradient of electric potential gives the _____ field.

Pilot questions 2.1

1. The gradient of a scalar field points in the direction of: A. Minimum decrease B. Maximum increase C. Constant value D. None of the above (Linked to SLO 2.1)

2. The gradient of a scalar field is: A. A scalar B. A vector C. A matrix D. None of the above (Linked to SLO 2.1)
3. If the gradient of a scalar field is zero, the field is: A. Increasing B. Decreasing C. Constant D. None of the above (Linked to SLO 2.1)
4. In heat transfer, the gradient of temperature indicates: A. Direction of heat flow B. Magnitude of heat capacity C. Rate of cooling D. None of the above (Linked to SLO 2.1)
5. In electrostatics, the gradient of electric potential gives: A. Magnetic field B. Electric field C. Gravitational field D. None of the above (Linked to SLO 2.1)

2.2 Divergence of Vector Fields

The **divergence** is a scalar operator that acts on a vector field. A **vector field** is a function that assigns a vector to every point in space, such as velocity in fluid flow or electric field in electromagnetism. The divergence of a vector field measures the net rate at which the field vectors are spreading out (or converging) from a point.

Fill in the blank: The divergence of a vector field measures the net rate at which the field vectors _____ from a point.

2.2.1 Definition and interpretation of divergence

If $F(x,y,z)=F_xi+F_yj+F_zk$ is a vector field, then its divergence is defined as:

$$F=F_{xx}+F_{yy}+F_{zz}$$

This scalar quantity indicates whether the field is acting like a source (positive divergence) or a sink (negative divergence). For example, in fluid flow, positive divergence means fluid is spreading out from a point, while negative divergence means fluid is converging towards a point.

Divergence of a vector field in fluid flow

Fill in the blank: Positive divergence indicates a _____, while negative divergence indicates a _____.

2.2.2 Properties of divergence

The divergence has several important properties:

- It is a scalar quantity.
- It measures the net outflow or inflow of a vector field at a point.

- If divergence is zero, the field is said to be **solenoidal**, meaning there is no net source or sink.
- Divergence depends on the spatial variation of the components of the vector field.

Properties of divergence Short description: Box summarising the main properties of divergence.

Fill in the blank: A vector field with zero divergence is called _____.

2.2.3 Applications in fluid flow and electromagnetism

- In **fluid dynamics**, divergence of velocity field indicates whether fluid is compressing or expanding at a point.
- In **electromagnetism**, divergence of the electric field is related to charge density by Gauss's law:

$$\nabla \cdot \mathbf{E} = \frac{\rho}{\epsilon_0}$$

where ρ is charge density and ϵ_0 is permittivity of free space.

- In **heat transfer**, divergence of heat flux relates to the rate of heat generation or absorption.

Divergence of electric field lines around charges

Fill in the blank: In electromagnetism, divergence of the electric field is related to _____ density.

Pilot questions 2.2

1. The divergence of a vector field is: A. A vector B. A scalar C. A matrix D. None of the above (Linked to SLO 2.2)
2. Positive divergence indicates: A. A sink B. A source C. A constant field D. None of the above (Linked to SLO 2.2)
3. A vector field with zero divergence is called: A. Solenoidal B. Rotational C. Constant D. None of the above (Linked to SLO 2.2)

4. In fluid dynamics, divergence of velocity field indicates: A. Rotation of fluid
B. Compression or expansion of fluid C. Constant velocity D. None of the above (Linked to SLO 2.2)
5. In electromagnetism, divergence of the electric field is related to: A. Magnetic flux B. Charge density C. Current density D. None of the above (Linked to SLO 2.2)

2.3 Curl of Vector Fields

The **curl** is a vector operator that acts on a vector field. It measures the tendency of the field to rotate around a point. In physical terms, curl describes the local rotational motion of a vector field, such as the swirling of fluid or the circulation of magnetic fields.

Fill in the blank: The curl of a vector field measures the tendency of the field to _____ around a point.

2.3.1 Definition and interpretation of curl

If $F(x,y,z)=F_xi+F_yj+F_zk$, then its curl is defined as:

$$F=F_yz i+F_zx j+F_xy k$$

This vector points in the axis of rotation and its magnitude indicates the strength of rotation.

Curl of a vector field showing rotational tendency

Fill in the blank: The curl of a vector field is defined as $\nabla \times F$, which produces a _____ quantity.

2.3.2 Properties of curl

The curl has several important properties:

- It is a vector quantity.
- It measures the local rotation of a vector field.
- If curl is zero, the field is said to be **irrotational**.
- Curl depends on the spatial variation of the components of the vector field.

Properties of curl Short description: Box summarising the main properties of curl.

Fill in the blank: A vector field with zero curl is called _____.

2.3.3 Applications in rotation and circulation

- In **fluid dynamics**, curl of velocity field represents vorticity, which measures the local spinning motion of fluid.
- In **electromagnetism**, curl of the magnetic field is related to current density by Ampère's law:

$$\nabla \times \mathbf{B} = \mu_0 \mathbf{J}$$

where $\mathbf{J}$ is current density and μ_0 is permeability of free space.

- In **engineering**, curl is used to analyse rotational effects in stress and strain fields.

Curl of velocity field representing vorticity in fluid flow

Fill in the blank: In fluid dynamics, curl of velocity field represents _____.

Pilot questions 2.3

1. The curl of a vector field is: A. A scalar B. A vector C. A matrix D. None of the above (Linked to SLO 2.3)
2. The curl of a vector field measures: A. Divergence B. Rotation C. Gradient D. None of the above (Linked to SLO 2.3)
3. A vector field with zero curl is called: A. Solenoidal B. Irrotational C. Constant D. None of the above (Linked to SLO 2.3)
4. In fluid dynamics, curl of velocity field represents: A. Displacement B. Vorticity C. Acceleration D. None of the above (Linked to SLO 2.3)
5. In electromagnetism, curl of the magnetic field is related to: A. Charge density B. Current density C. Electric potential D. None of the above (Linked to SLO 2.3)

2.4 Interrelationships of Gradient, Divergence, and Curl

The operators **gradient**, **divergence**, and **curl** are not isolated concepts; they are interconnected through vector identities and physical interpretations.

Understanding these relationships helps us see how scalar and vector fields interact and how these operators combine to describe complex phenomena in mathematics, physics, and engineering.

Fill in the blank: Gradient, divergence, and curl are interconnected through _____ identities and physical interpretations.

2.4.1 Vector identities involving gradient, divergence, and curl

Several important vector identities highlight the relationships among these operators:

- The divergence of the curl of any vector field is always zero:

$$\nabla \cdot (\nabla \times \mathbf{F}) = 0$$

- The curl of the gradient of any scalar field is always zero:

$$\nabla \times (\nabla \phi) = 0$$

- The Laplacian operator, defined as ∇^2 , can be expressed as the divergence of the gradient:

$$\nabla^2 \phi = \nabla \cdot (\nabla \phi)$$

Box summarising divergence of curl, curl of gradient, and Laplacian identity

Fill in the blank: The divergence of the curl of any vector field is always _____.

2.4.2 Physical significance of these relationships

- In **fluid dynamics**, the identity $\nabla \cdot (\nabla \times \mathbf{F}) = 0$ implies that rotational motion does not create sources or sinks.
- In **electromagnetism**, the identity $\nabla \times (\nabla \phi) = 0$ reflects that electric fields derived from potentials are irrotational.
- The Laplacian operator is widely used in heat conduction, wave equations, and diffusion processes, linking scalar fields to their spatial variations.

Diagram showing physical interpretations of Physical significance of vector identities

Fill in the blank: In electromagnetism, the identity $\nabla \times (\nabla \phi) = 0$ reflects that electric fields derived from potentials are _____.

2.4.3 Examples in applied contexts

- In **heat conduction**, the Laplacian of temperature field describes how heat diffuses through a medium.
- In **wave mechanics**, the Laplacian appears in the wave equation, linking displacement to spatial variation.
- In **engineering**, these identities simplify calculations in stress analysis and fluid modelling.

Laplacian in applied contexts

Fill in the blank: In heat conduction, the Laplacian of temperature field describes how heat _____ through a medium.

Pilot questions 2.4

1. The divergence of the curl of any vector field is: A. Zero B. Constant C. Infinite D. None of the above (Linked to SLO 2.4)
2. The curl of the gradient of any scalar field is: A. Zero B. Constant C. Infinite D. None of the above (Linked to SLO 2.4)
3. The Laplacian operator can be expressed as: A. Curl of divergence B. Divergence of gradient C. Gradient of curl D. None of the above (Linked to SLO 2.4)
4. In fluid dynamics, the identity $\nabla \cdot (\nabla \times \mathbf{F}) = 0$ implies: A. Rotational motion creates sources B. Rotational motion does not create sources or sinks C. Rotational motion creates sinks only D. None of the above (Linked to SLO 2.4)

Series Summary

This Series has explored the three fundamental vector operators—gradient, divergence, and curl—showing how they extend our ability to analyse scalar and vector fields. We began with the gradient of scalar fields, which points in

the direction of maximum increase and has applications in heat transfer, electrostatics, and geography. We then examined divergence of vector fields, interpreting it as a measure of sources and sinks, with applications in fluid dynamics and electromagnetism. Following that, we studied curl of vector fields, which captures rotational tendencies and is central to fluid vorticity and Ampère's law. Finally, we considered the interrelationships among these operators, highlighting vector identities and their physical significance in contexts such as heat conduction and wave mechanics.

Glossary of Terms

- **Curl:** A vector operator that measures the local rotation of a vector field, indicating how much the field tends to swirl around a point.
- **Divergence:** A scalar operator that measures the net outflow or inflow of a vector field at a point, showing whether the field behaves like a source or a sink.
- **Gradient:** A vector operator that acts on a scalar field, pointing in the direction of maximum increase and with magnitude equal to the rate of change.
- **Irrotational field:** A vector field with zero curl, meaning it has no local rotational tendency.
- **Laplacian:** A scalar operator defined as the divergence of the gradient of a scalar field, used to describe diffusion, heat conduction, and wave propagation.
- **Scalar field:** A function that assigns a single scalar value to every point in space, such as temperature or pressure.
- **Solenoidal field:** A vector field with zero divergence, meaning it has no net sources or sinks.
- **Vector field:** A function that assigns a vector to every point in space, such as velocity in fluid flow or electric field in electromagnetism.
- **Vorticity:** A physical quantity in fluid dynamics representing the curl of the velocity field, describing local spinning motion of the fluid.

Concept Check Questions 2

Objective questions

1. The gradient of a scalar field is: A. A scalar B. A vector C. A matrix D. None of the above (Linked to SLO 2.1)
2. Positive divergence indicates: A. A sink B. A source C. A constant field D. None of the above (Linked to SLO 2.2)
3. The curl of a vector field measures: A. Divergence B. Rotation C. Gradient D. None of the above (Linked to SLO 2.3)
4. The Laplacian operator can be expressed as: A. Curl of divergence B. Divergence of gradient C. Gradient of curl D. None of the above (Linked to SLO 2.4)

Short-answer questions

5. Define gradient and give one physical example. (Linked to SLO 2.1)
6. Explain what divergence of a vector field represents. (Linked to SLO 2.2)
7. State the physical meaning of curl in fluid dynamics. (Linked to SLO 2.3)
8. What does it mean when a vector field is solenoidal? (Linked to SLO 2.2)
9. Write down the identity involving curl of the gradient of a scalar field. (Linked to SLO 2.4)

Long-answer questions

10. Discuss the properties and applications of gradient in scalar fields. (Linked to SLO 2.1)
 - **Basic response:** Define gradient, explain its properties, and mention applications in heat transfer and electrostatics.
 - **Value-added response:** Provide detailed examples, such as gradient of temperature field indicating heat flow, and gradient of potential giving electric field.
11. Analyse the role of divergence in fluid dynamics and electromagnetism. (Linked to SLO 2.2)
 - **Basic response:** Explain divergence as a measure of sources and sinks, with examples in fluid compression and expansion.
 - **Value-added response:** Extend to Gauss's law in electromagnetism, showing how divergence of electric field relates to charge density.

12. Evaluate the significance of curl in describing rotation and circulation. (Linked to SLO 2.3)

- **Basic response:** Define curl and explain its role in fluid vorticity and Ampère's law.
- **Value-added response:** Provide examples of curl in engineering stress analysis and in describing rotational effects in vector fields.

13. Examine the interrelationships among gradient, divergence, and curl through vector identities. (Linked to SLO 2.4)

- **Basic response:** State identities such as divergence of curl equals zero and curl of gradient equals zero.
- **Value-added response:** Discuss their physical significance in fluid dynamics, electromagnetism, and heat conduction.

Answers to Concept Check Questions 2

1. B
2. B
3. B
4. B
5. Gradient is a vector operator that points in the direction of maximum increase of a scalar field. Example: gradient of temperature indicates heat flow direction.
6. Divergence measures the net outflow or inflow of a vector field at a point.
7. Curl in fluid dynamics represents vorticity, describing local spinning motion of fluid.
8. A solenoidal field has zero divergence, meaning no net sources or sinks.
9. The curl of the gradient of a scalar field is always zero: $\nabla \times (\nabla \phi) = 0$.
10. **Basic response:** Gradient is a vector pointing in the direction of maximum increase of a scalar field, used in heat transfer and electrostatics. **Value-added response:** Gradient of temperature shows heat flow direction, gradient of potential gives electric field, gradient of elevation gives slope in geography.

11. **Basic response:** Divergence measures sources and sinks, e.g. fluid expansion or compression. **Value-added response:** In electromagnetism, divergence of electric field relates to charge density via Gauss's law.
12. **Basic response:** Curl measures rotation, applied in fluid vorticity and Ampère's law. **Value-added response:** Curl is also used in engineering to analyse rotational effects in stress and strain fields.
13. **Basic response:** Divergence of curl equals zero, curl of gradient equals zero, Laplacian is divergence of gradient. **Value-added response:** These identities explain why rotational motion does not create sources, why electric fields from potentials are irrotational, and how Laplacian governs heat conduction and wave mechanics.

3 Line Integrals and Surface Integrals

Series Outline

- **Part 3.1: Line Integrals of Scalar and Vector Fields**
 - Definition of line integrals
 - Line integrals of scalar fields
 - Line integrals of vector fields
 - Applications in work and circulation
- **Part 3.2: Surface Integrals of Scalar and Vector Fields**
 - Definition of surface integrals
 - Surface integrals of scalar fields
 - Surface integrals of vector fields
 - Applications in flux and physical sciences
- **Part 3.3: Theorems of Vector Calculus**

- Green's theorem
- Stokes' theorem
- Divergence theorem
- Physical significance and applications

Introduction

In this Series we turn to line integrals and surface integrals, which extend the ideas of vector calculus into powerful tools for analysing scalar and vector fields over curves and surfaces. These integrals allow us to calculate quantities such as work, flux, and circulation, and they form the foundation for the great theorems of vector calculus.

The purpose of this Series is to help you understand how line and surface integrals are defined, how they are computed, and why they are important in mathematics, physics, and engineering. We begin with line integrals, exploring both scalar and vector cases and their applications in work and circulation. Next, we move to surface integrals, examining how they measure flux through surfaces and their role in physical sciences. Finally, we conclude with the major theorems of vector calculus—Green's theorem, Stokes' theorem, and the Divergence theorem—showing how they unify and simplify the evaluation of integrals in applied contexts.

Series Learning Outcomes

Upon completing this Series, you should be able to:

- SLO 3.1 define and compute line integrals of scalar and vector fields, and explain their applications in work and circulation,
- SLO 3.2 demonstrate how to evaluate surface integrals of scalar and vector fields, and interpret their role in measuring flux,
- SLO 3.3 apply Green's theorem, Stokes' theorem, and the Divergence theorem to simplify and evaluate integrals,
- SLO 3.4 analyse the physical significance of line and surface integrals, and the major vector calculus theorems in applied contexts.

3.1 Line Integrals of Scalar and Vector Fields

A line integral is an integral taken along a curve or path. It allows us to accumulate values of a scalar or vector field along that path. Line integrals are widely used in physics and engineering to calculate quantities such as work done by a force, or circulation of a vector field around a curve.

Fill in the blank: A line integral is an integral taken along a _____ or path.

3.1.1 Line integrals of scalar fields

If $\phi(x,y,z)$ is a scalar field and C is a curve parameterised by $r(t)$, then the line integral of ϕ along C is:

$$\int_C \phi \, ds$$

where ds is the differential arc length along the curve. This integral represents the accumulation of scalar values along the path.

Line integral of a scalar field along a curve

Fill in the blank: The line integral of a scalar field along a curve is expressed as $\int_C \phi \, ds$.

3.1.2 Line integrals of vector fields

If $F(x,y,z)$ is a vector field and C is a curve parameterised by $r(t)$, then the line integral of F along C is:

$$\int_C F \cdot dr$$

This integral measures the work done by the vector field along the curve.

Line integral of a vector field representing work

Fill in the blank: The line integral of a vector field along a curve is expressed as $\int_C F \cdot dr$.

3.1.3 Applications in work and circulation

- **Work:** In mechanics, the work done by a force along a path is given by the line integral of the force vector field.
- **Circulation:** In fluid dynamics, circulation is the line integral of velocity field around a closed curve, measuring the tendency of fluid to rotate.
- **Electromagnetism:** Line integrals are used to calculate electromotive force along a circuit.

Circulation as line integral of velocity field

Fill in the blank: In fluid dynamics, circulation is the line integral of velocity field around a _____ curve.

Pilot questions 3.1

1. A line integral is taken along a: A. Point B. Curve C. Surface D. None of the above (Linked to SLO 3.1)
2. The line integral of a scalar field along a curve is expressed as: A. $C \, ds$ B. $C \mathbf{F} \cdot d\mathbf{r}$ C. $C \, dA$ D. None of the above (Linked to SLO 3.1)
3. The line integral of a vector field along a curve is expressed as: A. $C \, ds$ B. $C \mathbf{F} \cdot d\mathbf{r}$ C. $C \, dA$ D. None of the above (Linked to SLO 3.1)
4. Work done by a force along a path is given by: A. A dot product B. A line integral C. A cross product D. None of the above (Linked to SLO 3.1)
5. Circulation in fluid dynamics is the line integral of velocity field around a: A. Point B. Closed curve C. Surface D. None of the above (Linked to SLO 3.1)

3.2 Surface Integrals of Scalar and Vector Fields

A **surface integral** is an integral taken over a surface in three-dimensional space. It allows us to accumulate values of a scalar or vector field across a surface. Surface integrals are essential in physics and engineering, especially for calculating flux through surfaces.

Fill in the blank: A surface integral is an integral taken over a _____ in three-dimensional space.

3.2.1 Surface integrals of scalar fields

If $\phi(x,y,z)$ is a scalar field and S is a surface, then the surface integral of over S is:

$$\iint_S \phi \, dS$$

where dS is the differential element of surface area. This integral represents the accumulation of scalar values across the surface.

Surface integral of a scalar field

Fill in the blank: The surface integral of a scalar field over a surface is expressed as $\iint S \, dS$.

3.2.2 Surface integrals of vector fields

If $F(x,y,z)$ is a vector field and S is a surface with unit normal vector n , then the surface integral of F over S is:

$$\iint S F n \, dS$$

This integral measures the flux of the vector field through the surface.

Surface integral of a vector field representing flux

Fill in the blank: The surface integral of a vector field over a surface is expressed as $\iint S F n \, dS$.

3.2.3 Applications in flux and physical sciences

- **Flux in fluid dynamics:** Surface integrals measure the amount of fluid passing through a surface.
- **Electromagnetism:** Surface integrals of electric or magnetic fields calculate flux, central to Gauss's law and Faraday's law.
- **Heat transfer:** Surface integrals of heat flux describe energy transfer across boundaries.

Electric flux as surface integral of electric field

Fill in the blank: In electromagnetism, surface integrals of electric field are central to _____ law.

Pilot questions 3.2

1. A surface integral is taken over a: A. Point B. Curve C. Surface D. None of the above (Linked to SLO 3.2)
2. The surface integral of a scalar field over a surface is expressed as: A. $\iint S \, dS$ B. $C \, ds$ C. $\iint S F n \, dS$ D. None of the above (Linked to SLO 3.2)

3. The surface integral of a vector field over a surface is expressed as: A. $\iint_S d\mathbf{S} \cdot \mathbf{B}$ B. $\iint_S \mathbf{F} \cdot \mathbf{n} dS$ C. $\oint_C \mathbf{F} \cdot d\mathbf{r}$ D. None of the above (Linked to SLO 3.2)
4. The surface integral of a vector field measures: A. Work B. Flux C. Circulation D. None of the above (Linked to SLO 3.2)
5. In electromagnetism, surface integrals of electric field are central to: A. Ampère's law B. Gauss's law C. Faraday's law D. None of the above (Linked to SLO 3.2)

3.3 Theorems of Vector Calculus

The **theorems of vector calculus** provide powerful connections between line integrals, surface integrals, and volume integrals. They allow us to transform integrals from one domain to another, simplifying calculations and revealing deep physical insights.

Fill in the blank: The theorems of vector calculus connect line integrals, surface integrals, and _____ integrals.

3.3.1 Green's theorem

Green's theorem relates a line integral around a simple closed curve C to a double integral over the region R bounded by C :

$$\oint_C (P dx + Q dy) = \iint_R (Q_x - P_y) dA$$

This theorem is useful in planar regions and has applications in fluid flow and circulation.

Green's theorem relating line integral to double integral

Fill in the blank: Green's theorem relates a line integral around a closed curve to a _____ integral over the region it encloses.

3.3.2 Stokes' theorem

Stokes' theorem generalises Green's theorem to three dimensions. It relates a line integral around a closed curve C to a surface integral of curl over the surface S bounded by C :

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = \iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} dS$$

This theorem is central in electromagnetism and fluid dynamics.

Stokes' theorem relating line integral to surface integral of curl AI prompt:

Fill in the blank: Stokes' theorem relates a line integral around a closed curve to a _____ integral of curl over the surface it bounds.

3.3.3 Divergence theorem

The Divergence theorem (Gauss's theorem) relates a surface integral of a vector field over a closed surface S to a volume integral of divergence over the region V enclosed by S :

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, dS = \iiint_V (\nabla \cdot \mathbf{F}) \, dV$$

This theorem is widely used in electromagnetism, fluid dynamics, and heat transfer.

Divergence theorem relating surface integral to volume integral

Fill in the blank: The Divergence theorem relates a surface integral over a closed surface to a _____ integral of divergence over the volume it encloses.

3.3.4 Physical significance and applications

- **Green's theorem:** circulation and area integrals in planar regions.
- **Stokes' theorem:** circulation and curl in three-dimensional fields.
- **Divergence theorem:** flux and sources in electromagnetism and fluid dynamics.

Applications of vector calculus theorems

Fill in the blank: The Divergence theorem is also known as _____ theorem.

Pilot questions 3.3

1. Green's theorem relates a line integral around a closed curve to: A. A surface integral B. A double integral over the region C. A volume integral D. None of the above (Linked to SLO 3.3)
2. Stokes' theorem relates a line integral around a closed curve to: A. A surface integral of curl B. A volume integral of divergence C. A scalar integral D. None of the above (Linked to SLO 3.3)

3. The Divergence theorem relates a surface integral over a closed surface to:
A. A line integral B. A volume integral of divergence C. A double integral
D. None of the above (Linked to SLO 3.3)
4. Green's theorem is primarily applied in: A. Planar regions B. Three-dimensional fields C. Volume integrals D. None of the above (Linked to SLO 3.3)
5. The Divergence theorem is also known as: A. Stokes' theorem B. Gauss's theorem C. Green's theorem D. None of the above (Linked to SLO 3.3)

Series Summary

This Series has explored **line integrals and surface integrals**, two fundamental tools in vector calculus that extend differentiation into integration over curves and surfaces. We began with line integrals, distinguishing between scalar and vector cases, and saw how they are applied to compute work, circulation, and electromotive force. Next, we studied surface integrals, both for scalar and vector fields, and learned how they measure flux through surfaces in contexts such as fluid dynamics, electromagnetism, and heat transfer. Finally, we examined the major theorems of vector calculus—Green's theorem, Stokes' theorem, and the Divergence theorem—which unify line, surface, and volume integrals, providing elegant ways to simplify calculations and interpret physical phenomena. By completing this Series, you should now be able to define and compute line integrals of scalar and vector fields (SLO 3.1), evaluate surface integrals and interpret their role in flux (SLO 3.2), apply Green's, Stokes', and Divergence theorems to transform integrals (SLO 3.3), and analyse their physical significance in applied contexts such as fluid flow, electromagnetism, and heat transfer (SLO 3.4). These skills form the backbone of applied vector calculus and are indispensable in advanced mathematics, physics, and engineering.

Glossary of Terms

- **Circulation:** The line integral of a velocity field around a closed curve, measuring the tendency of fluid to rotate.
- **Flux:** The surface integral of a vector field through a surface, representing the quantity passing through that surface.
- **Gauss's theorem:** Another name for the Divergence theorem, relating surface integrals to volume integrals.
- **Green's theorem:** A theorem that relates a line integral around a closed curve in a plane to a double integral over the region it encloses.
- **Line integral:** An integral taken along a curve, used to accumulate scalar or vector field values along a path.

- **Scalar field:** A function assigning a single scalar value to each point in space.
- **Stokes' theorem:** A theorem that relates a line integral around a closed curve to a surface integral of curl over the surface it bounds.
- **Surface integral:** An integral taken over a surface, used to accumulate scalar or vector field values across a surface.
- **Vector field:** A function assigning a vector to each point in space, such as velocity or force.
- **Work:** In mechanics, the line integral of a force vector field along a path, representing energy transfer.

Concept Check Questions 3

Objective questions

1. A line integral is taken along a: A. Point B. Curve C. Surface D. None of the above (Linked to SLO 3.1)
2. The surface integral of a vector field over a surface is expressed as: A. $\iint_S d\mathbf{S} \cdot \mathbf{B}$ B. $\iint_S \mathbf{F} \cdot d\mathbf{S}$ C. $\oint \mathbf{F} \cdot d\mathbf{r}$ D. None of the above (Linked to SLO 3.2)
3. Green's theorem relates a line integral around a closed curve to: A. A surface integral B. A double integral over the region C. A volume integral D. None of the above (Linked to SLO 3.3)
4. Stokes' theorem relates a line integral around a closed curve to: A. A surface integral of curl B. A volume integral of divergence C. A scalar integral D. None of the above (Linked to SLO 3.3)
5. The Divergence theorem is also known as: A. Stokes' theorem B. Gauss's theorem C. Green's theorem D. None of the above (Linked to SLO 3.3)

Short-answer questions

6. Define a line integral and give one physical example. (Linked to SLO 3.1)
7. Explain what a surface integral of a vector field represents. (Linked to SLO 3.2)
8. State Green's theorem in words. (Linked to SLO 3.3)
9. What does Stokes' theorem generalise? (Linked to SLO 3.3)

10. Write down the Divergence theorem in mathematical form. (Linked to SLO 3.3)

Long-answer questions

11. Discuss the properties and applications of line integrals in scalar and vector fields. (Linked to SLO 3.1)

- **Basic response:** Define line integrals and explain their use in work and circulation.
- **Value-added response:** Provide detailed examples in mechanics, fluid dynamics, and electromagnetism.

12. Analyse the role of surface integrals in measuring flux in physical sciences. (Linked to SLO 3.2)

- **Basic response:** Define surface integrals and explain their role in flux.
- **Value-added response:** Extend to applications in Gauss's law, fluid flow, and heat transfer.

13. Evaluate the significance of Green's, Stokes', and Divergence theorems in vector calculus. (Linked to SLO 3.3)

- **Basic response:** State each theorem and explain its mathematical relationship.
- **Value-added response:** Discuss their physical significance in fluid dynamics, electromagnetism, and wave mechanics.

Introduction

In this Series we focus on the integral theorems of vector calculus—Green's theorem, Stokes' theorem, and the Divergence theorem—and their wide-ranging applications. These theorems unify line, surface, and volume integrals, providing elegant ways to transform complex integrals into simpler forms. They are not only mathematically powerful but also physically meaningful, forming the backbone of applied mathematics in physics and engineering.

The purpose of this Series is to help you understand the statements, proofs, and interpretations of these theorems, and to apply them in practical contexts. We begin with Green's theorem in the plane, which connects line integrals around closed curves to double integrals over regions. Next, we explore Stokes' theorem in three dimensions, which generalises Green's theorem by relating line integrals to surface integrals of curl. We then study the Divergence theorem (Gauss's theorem), which links surface integrals over closed surfaces to volume integrals of divergence. Finally, we examine applied contexts, showing how these theorems are used in fluid dynamics, electromagnetism, and heat transfer.

Series Learning Outcomes

Upon completing this Series, you should be able to:

- SLO 4.1 define and apply Green's theorem in the plane, and interpret its significance in circulation and area integrals,
- SLO 4.2 demonstrate the use of Stokes' theorem in three dimensions, and explain its role in relating curl and circulation,
- SLO 4.3 evaluate the Divergence theorem (Gauss's theorem), and interpret its applications in flux and sources,
- SLO 4.4 analyse the physical significance of integral theorems in applied contexts such as fluid dynamics, electromagnetism, and heat transfer.

4.1 Green's Theorem in the Plane

Green's theorem is one of the cornerstone results in vector calculus. It provides a relationship between a line integral around a closed curve and a double integral over the region enclosed by that curve.

Fill in the blank: Green's theorem relates a line integral around a closed curve to a _____ integral over the region it encloses.

4.1.1 Statement of Green's theorem

If C is a positively oriented, simple closed curve in the plane, and R is the region bounded by C , then for functions $P(x,y)$ and $Q(x,y)$ with continuous partial derivatives:

$$\oint_C (P dx + Q dy) = \iint_R (Q_x - P_y) dA$$

This theorem transforms a line integral into a double integral, simplifying calculations in many cases.

Green's Theorem: Relating Line & Double Integrals

1. Line Integral (Circulation)

$$\oint_C (P dx + Q dy)$$

2. Double Integral (Curl Density)

$$\frac{\Delta \Delta}{\Delta \Delta} R \left(\frac{dQ}{dx} - \left(P \frac{1}{dy} \right) \right) dA$$

$$\oint_C (P dx + Q dy) = \frac{++}{\Delta \Delta} \left(\frac{dQ}{dx} - (P_{yy}) \right) dA$$

Green's Theorem relates the line integral of a vector field around a simple closed curve C to a double integral of the curl of the vector field over the region R it encloses. It shows that the total circulation along the boundary is equal to the sum of the infinitesimal rotations within the region.

Green's theorem relating line integral to double integral

4.1.2 Interpretation of Green's theorem

- Circulation interpretation: The line integral around the boundary measures circulation, while the double integral measures curl inside the region.
- Area interpretation: In some cases, Green's theorem can be used to compute areas of regions using line integrals.

Fill in the blank: Green's theorem can be used to compute _____ of regions using line integrals.

4.1.3 Applications in planar circulation and area integrals

- Fluid flow: Green's theorem relates circulation around a boundary to vorticity inside the region.
- Electromagnetism: It connects boundary integrals of fields to area integrals of curl.
- Geometry: Used to compute areas of irregular regions by converting to line integrals.

Green's Theorem: Fluid Flow & Circulation

Relating Boundary Circulation to Enticity

1. Line Integral (Circulation)

$$\oint_C \mathbf{F} \cdot d\mathbf{r}$$

2. Enoled Integral (Curl Density)

$$\iint_R (\nabla \times \mathbf{F}) \cdot d\mathbf{A}$$

$$\oint_C (P dx + Q dy) = \iint_R \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dA$$

Green's Theorem relates for fluid flow states that the line integral around the total closed curve C to the closed integral boundary. This it encloses along to the sum of the sum of the vorticity within the region.

Application of Green's theorem in fluid flow

Fill in the blank: In fluid flow, Green's theorem relates circulation around a boundary to _____ inside the region.

4.1.4 Worked example

Example: Use Green's theorem to evaluate $\oint_C (x^2 dx + y^2 dy)$, where C is the unit circle $x^2 + y^2 = 1$.

Solution:

$$Q_x - P_y = (y^2)_x - (x^2)_y = 0 - 0 = 0$$

Thus,

$$\oint_C (x^2 dx + y^2 dy) = \iint_R 0 \, dA = 0$$

Fill in the blank: In the worked example, the line integral around the unit circle evaluates to _____.

Pilot questions 4.1

1. Green's theorem relates a line integral around a closed curve to: A. A surface integral B. A double integral over the region C. A volume integral D. None of the above (Linked to SLO 4.1)
2. The formula for Green's theorem is: A. $\oint_C (P dx + Q dy) = \iint_R Q_x - P_y dA$. B. $\oint_C \mathbf{F} \cdot d\mathbf{r} = \iint_S (\mathbf{F} \cdot \mathbf{n}) dS$. C. $\iint_S \mathbf{F} \cdot \mathbf{n} dS = \iiint_V (\nabla \cdot \mathbf{F}) dV$. D. None of the above (Linked to SLO 4.1)
3. Green's theorem can be used to compute: A. Length of curves B. Area of regions C. Volume of solids D. None of the above (Linked to SLO 4.1)
4. In fluid flow, Green's theorem relates circulation around a boundary to: A. Divergence inside the region B. Vorticity inside the region C. Gradient inside the region D. None of the above (Linked to SLO 4.1)
5. In the worked example, the line integral around the unit circle evaluates to: A. 1 B. 0 C. Infinity D. None of the above (Linked to SLO 4.1)

4.2 Stokes' Theorem in Three Dimensions

Stokes' theorem is a fundamental result in vector calculus that generalises Green's theorem to three dimensions. It connects a line integral around a closed curve to a surface integral of curl over the surface bounded by that curve.

Fill in the blank: Stokes' theorem relates a line integral around a closed curve to a _____ integral of curl over the surface it bounds.

4.2.1 Statement of Stokes' theorem

If S is an oriented smooth surface bounded by a simple closed curve C , and F is a vector field with continuous partial derivatives, then:

$$\oint_C F \cdot dr = \iint_S (\nabla \times F) \cdot n \, dS$$

This theorem transforms a line integral into a surface integral, making it easier to evaluate circulation in three-dimensional fields.

Stokes's Theorem: Relating Surface & Line Integrals

Swirling & Circulation Density

1. Line Integral (Circulation)

$$\oint_C \mathbf{F} \cdot d\mathbf{a}$$

2. Surface Integral (Flux of Curl Density)

$$\iint_S (\nabla \times \mathbf{F}) \cdot d\mathbf{a}$$

$$\oint_C \mathbf{F} \cdot d\mathbf{a} = \iint_S (\nabla \times \mathbf{F}) \cdot d\mathbf{a}$$

Stokes' Theorem relates the line integral of a vector field around a closed curve C to the flux of the curl of the vector field through any surface S that has C as its boundary. It states that the circulation along the boundary curve is equal to the total 'swirling' or 'vorticity' passing through the surface.

Source: OER Math & Physics

Stokes' theorem relating line integral to surface integral of curl

4.2.2 Interpretation of Stokes' theorem

- Circulation interpretation: The line integral around the boundary curve measures circulation, while the surface integral measures curl across the surface.
- Generalisation: Stokes' theorem generalises Green's theorem from two-dimensional regions to three-dimensional surfaces.

Fill in the blank: Stokes' theorem generalises _____ theorem from two dimensions to three dimensions.

4.2.3 Applications in curl and circulation

- Fluid dynamics: Stokes' theorem relates circulation around a boundary curve to vorticity across the surface.
- Electromagnetism: It is central to Maxwell's equations, connecting electromotive force around a loop to the changing magnetic field through the surface.
- Engineering: Used in stress analysis and modelling rotational effects in vector fields.

Stokes's Theorem: Linking EMF & Magnetic Flux in Electromagnetism

1. Electromotive EMF - Circulation

$$\oint_C \mathbf{E} \cdot d\mathbf{r}$$

2. Magnetic Flux (Surface Integral)

$$\iint_S (\nabla \times \mathbf{B}) \cdot \mathbf{n} \, dA$$

$$\oint_C \mathbf{E} \cdot d\mathbf{r} = \iint_S (\nabla \times \mathbf{B}) \cdot \mathbf{n} \, dA$$

Stokes' Theorem, as applied in Maxwell's equations (Faraday, Law), relates the electromotive force (EMF) around a closed loop 'C' to the total magnetic flux through the surface 'S' that is bounded by 'C'. This is a fundamental principle explaining how a changing magnetic field induces an electric field.

Application of Stokes' theorem in electromagnetism

Fill in the blank: In electromagnetism, Stokes' theorem connects electromotive force around a loop to the changing _____ field through the surface.

4.2.4 Worked example

Example: Evaluate $\oint_C \mathbf{F} \cdot d\mathbf{r}$ for $\mathbf{F} = (y, -x, 0)$, where C is the unit circle in the xy -plane.

Solution:

$$\mathbf{F} = (0, 0, -1) - (1, -1, 0) = (-1, 1, 0)$$

The surface S is the unit disk in the xy -plane, with normal vector $\mathbf{n}=(0,0,1)$.

$$\iint_S (\mathbf{F}) \cdot \mathbf{n} \, dS = \iint_S (0,0,-2) \cdot (0,0,1) \, dS = -2 \iint_S dS$$

Area of unit disk = .

$$\iint_S (\mathbf{F}) \cdot \mathbf{n} \, dS = -2\pi$$

Thus,

$$\mathbf{C} \cdot d\mathbf{r} = -2\pi$$

Fill in the blank: In the worked example, the line integral around the unit circle evaluates to _____.

Pilot questions 4.2

1. Stokes' theorem relates a line integral around a closed curve to: A. A surface integral of curl B. A volume integral of divergence C. A scalar integral D. None of the above (Linked to SLO 4.2)
2. The formula for Stokes' theorem is: A. $\mathbf{C} \cdot d\mathbf{r} = \iint_S (\mathbf{F}) \cdot \mathbf{n} \, dS$. $\oint_C (P \, dx + Q \, dy) = \iint_R Q_x - P_y \, dA$. $\iint_S \mathbf{F} \cdot \mathbf{n} \, dS = \iiint_V (\nabla \cdot \mathbf{F}) \, dV$. None of the above (Linked to SLO 4.2)
3. Stokes' theorem generalises: A. Divergence theorem B. Green's theorem C. Gauss's theorem D. None of the above (Linked to SLO 4.2)
4. In electromagnetism, Stokes' theorem connects electromotive force around a loop to the changing: A. Electric field B. Magnetic field C. Heat field D. None of the above (Linked to SLO 4.2)
5. In the worked example, the line integral around the unit circle evaluates to: A. 0 B. C. -2π D. None of the above (Linked to SLO 4.2)

4.3 Divergence Theorem (Gauss's Theorem)

The Divergence theorem—also known as Gauss's theorem—is a fundamental result in vector calculus that connects a surface integral over a closed surface to a volume integral over the region it encloses.

Fill in the blank: The Divergence theorem relates a surface integral over a closed surface to a _____ integral of divergence over the volume it encloses.

4.3.1 Statement of Divergence theorem

If V is a solid region in space bounded by a closed surface S , and F is a vector field with continuous partial derivatives, then:

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, dS = \iiint_V (\nabla \cdot \mathbf{F}) \, dV$$

This theorem transforms a surface integral into a volume integral, simplifying flux calculations.

Divergence Theorem: Relating Volume & Surface Integrals

Gauss's Law for Vector Fields

1. Volume Integral (Total Divergence)

$$\iiint_V (\nabla \cdot \mathbf{F}) \, dV$$

2. Surface Integral (Total Flux)

$$\iint_S (\mathbf{F} \cdot \mathbf{n}) \, dA$$

$$\iiint_V (\nabla \cdot \mathbf{F}) \, dV = \iint_S (\mathbf{F} \cdot \mathbf{n}) \, dA$$

The Divergence Theorem relates the total outward flux of the vector field through the closed surface S to the total divergence of the field in the volume V it encloses. It shows that net flow out of the volume is equal to the sum of divergences (sources). This is a fundamental concept in fluid dynamics and electromagnetism (Gauss's law).

Divergence theorem relating surface integral to volume integral

4.3.2 Interpretation of Divergence theorem

- Flux interpretation: The surface integral measures flux through the boundary, while the volume integral measures divergence inside the region.
- Source interpretation: Divergence represents sources or sinks of the field inside the volume.

Fill in the blank: Divergence represents sources or _____ of the field inside the volume.

4.3.3 Applications in flux and sources

- Fluid dynamics: Relates net outflow of fluid through a boundary to sources inside the volume.
- Electromagnetism: Central to Gauss's law, connecting electric flux through a closed surface to charge enclosed.
- Heat transfer: Used to model energy flow and sources inside a region.

Gauss's Law: Divergence Theorem for Electric Fields

1. Volume Integral (Charge Density)

$$\rho = \frac{dq}{dV}$$

2. Surface Integral (Electric Flux)

$$\Phi_E = \oint_S (\mathbf{E} \cdot \mathbf{n}) dA$$

$$\oint_S \mathbf{E} \cdot d\mathbf{A} = \frac{1}{\epsilon_0} \int_V (\nabla \cdot \mathbf{E}) dV = \frac{Q_{\text{enclosed}}}{\epsilon_0}$$

Gauss' Law, derived from the Divergence Theorem, states that the electric flux through any closed surface is equal to the net charge enclosed divided by the permittivity of free space. It relates the electric flux density to the charge density.

Source: OER Math & Physics

Application of Divergence theorem in Gauss's law

Fill in the blank: In electromagnetism, the Divergence theorem is central to _____ law.

4.3.4 Worked example

Example: Verify the Divergence theorem for $\mathbf{F}=(x,y,z)$ over the unit cube $0 \leq x,y,z \leq 1$.

Solution:

$$\mathbf{F} = x\mathbf{i} + y\mathbf{j} + z\mathbf{k} \Rightarrow \nabla \cdot \mathbf{F} = 1 + 1 + 1 = 3$$

Volume integral:

$$\iiint_V (F) \, dV = \iiint_V 3 \, dV = 3 \cdot (1 \cdot 1 \cdot 1) = 3$$

Surface integral: Flux through each face of the cube also sums to 3. Thus, the Divergence theorem holds.

Fill in the blank: In the worked example, the Divergence theorem evaluates to _____.

Pilot questions 4.3

1. The Divergence theorem relates a surface integral over a closed surface to:
A. A line integral B. A volume integral of divergence C. A double integral
D. None of the above (Linked to SLO 4.3)
2. The formula for Divergence theorem is: A. $\iint_S \mathbf{F} \cdot \mathbf{n} \, dS = \iiint_V (\nabla \cdot \mathbf{F}) \, dV$.
B. $\oint_C (P \, dx + Q \, dy) = \iint_R (Q_x - P_y) \, dA$. C. $\oint_C \mathbf{F} \cdot d\mathbf{r} = \iint_S (\nabla \times \mathbf{F}) \cdot \mathbf{n} \, dS$. D. None of the above
(Linked to SLO 4.3)
3. Divergence represents: A. Sources or sinks of the field B. Circulation of the field
C. Gradient of the field D. None of the above (Linked to SLO 4.3)
4. In electromagnetism, the Divergence theorem is central to: A. Ampère's law
B. Gauss's law C. Faraday's law D. None of the above (Linked to SLO 4.3)
5. In the worked example, the Divergence theorem evaluates to: A. 1 B. 2 C. 3
D. None of the above (Linked to SLO 4.3)

4.4 Applied Contexts of Integral Theorems

The integral theorems of vector calculus—Green's, Stokes', and Divergence—are not just abstract mathematical results. They have profound applications in physics, engineering, and applied sciences, where they simplify complex problems and provide physical meaning to integrals.

Fill in the blank: Integral theorems are widely applied in physics, engineering, and _____ sciences.

4.4.1 Fluid dynamics

- Green's theorem: Used to relate circulation around a boundary to vorticity inside a region in 2D flows.
- Stokes' theorem: Connects circulation around a curve to curl across a surface, useful in analysing rotational flow.

- Divergence theorem: Relates net outflow of fluid through a boundary to sources or sinks inside the volume.

Fluid Dynamics: Flow, Circulation & Sources

Vector Calculus Theorems

1. Green's Theorem (2D Circulation)  $\oint_C \mathbf{v} \cdot d\mathbf{r} = \iint_A (\nabla \times \mathbf{v}) \cdot \mathbf{n} \, dA$	2. Stokes' Theorem (3D Circulation)  $\oint_C \mathbf{v} \cdot d\mathbf{r} = \iint_S (\nabla \times \mathbf{v}) \cdot \mathbf{n} \, dA$	3. Divergence Theorem (Flux & Sources)  $\oint_S \mathbf{v} \cdot \mathbf{n} \, dA = \iiint_V (\nabla \cdot \mathbf{v}) \, dV$
--	--	--

These fundamental theorems link the behavior of fluid flow on boundaries to the properties within regions. Green's and Stokes' relate circulation to vorticity (swirling), while the Divergence Theorem connects total flux through a surface to the net sources and sinks within the volume (divergence), and mass conservation in fluid mechanics.

 Source: OER Math & Physics

Applications of integral theorems in fluid dynamics

4.4.2 Electromagnetism

- Green's theorem: Applied in planar field problems.
- Stokes' theorem: Central to Maxwell's equations, relating electromotive force around a loop to changing magnetic flux.
- Divergence theorem: Basis of Gauss's law, connecting electric flux through a closed surface to charge enclosed.

Maxwell Equations

Vector Calculus Interpretations & Physical Meaning

Differential Forms

Gauss's Law (Electric)

$$\nabla \cdot \mathbf{E} = \rho / \epsilon_0$$

Gauss's Law (Magnetic)

$$\nabla \cdot \mathbf{B} = 0$$

Faraday Law (Electromotive Force)

$$\nabla \times \mathbf{E} = -\partial \mathbf{B} / \partial t$$

$$\nabla \times \mathbf{B} = \mu_0 \mathbf{J} + \mu_0 \epsilon_0 \partial \mathbf{E} / \partial t$$

Ampère-Maxwell Law

Integral Forms (Physical Meaning)

Electric Flux from Charge (Sources)

$$\Phi_S = \oint_S \mathbf{E} \cdot d\mathbf{A} = \frac{1}{\epsilon_0} Q_{\text{enclosed}}$$

Changing B-field creates (E-field (EMF))

$$\oint_C \mathbf{E} \cdot d\mathbf{r} = -\frac{d}{dt} \int_S \mathbf{B} \cdot d\mathbf{A}$$

No Magnetic Monopoles (No Sources)

$$\oint_S \mathbf{B} \cdot d\mathbf{A} = 0$$

Current & Changing E-field create B-field)

$$\oint_C \mathbf{B} \cdot d\mathbf{r} = \mu_0 \left(\int_S \mathbf{J} \cdot d\mathbf{A} + \epsilon_0 \frac{d}{dt} \int_S \mathbf{E} \cdot d\mathbf{A} \right)$$

These four fundamental equations describe how electric ($\mathbf{E}$) and magnetic ($\mathbf{B}$) fields interact, generate them, and relate them to charges and currents. They form the foundation of classical electromagnetism.

Applications of integral theorems in electromagnetism

Fill in the blank: In electromagnetism, the Divergence theorem is central to _____ law.

4.4.3 Heat transfer and engineering applications

- Divergence theorem: Used to model energy flow and heat sources inside a region.
- Stokes' theorem: Applied in stress analysis and rotational effects in engineering fields.

- Green's theorem: Helps simplify planar heat conduction problems.\

Heat Transfer & the Divergence Theorem

Linking Heat Flux & Heat Sources

1. Volume Integral (Total Sources)

$$\iiint_V (\nabla \cdot q) dV$$

2. Surface Integral (Total Flux)

$$\oiint_S (q \cdot n) dA$$

$$\iiint_V (\nabla \cdot q) dV = \oiint_S (q \cdot n) dA$$

The Divergence Theorem relates the total heat flux across the closed surface 'S' to total heat sources within the enclosed volume V. It shows that the net outward flow from the region is equal to the total heat generated inside the region, minus any heat consumed. This is a fundamental principle in heat transfer and thermodynamics.

Source: OER Math & Physics

Applications of integral theorems in heat transfer

Fill in the blank: In heat transfer, the Divergence theorem is used to model _____ flow and sources inside a region.

Pilot questions 4.4

1. Integral theorems are widely applied in: A. Physics B. Engineering C. Applied sciences D. All of the above (Linked to SLO 4.4)
2. In fluid dynamics, Stokes' theorem connects circulation around a curve to: A. Divergence B. Curl C. Gradient D. None of the above (Linked to SLO 4.4)
3. In electromagnetism, the Divergence theorem is central to: A. Ampère's law B. Gauss's law C. Faraday's law D. None of the above (Linked to SLO 4.4)
4. In heat transfer, the Divergence theorem is used to model: A. Energy flow and sources B. Circulation C. Gradient D. None of the above (Linked to SLO 4.4)
5. Stokes' theorem is central to: A. Maxwell's equations B. Newton's laws C. Fourier's law D. None of the above (Linked to SLO 4.4)

Series Summary

This Series has explored the integral theorems of vector calculus—Green's theorem, Stokes' theorem, and the Divergence theorem—and their applications. We began with Green's theorem in the plane, which connects line integrals around closed curves to double integrals over regions, offering insights into circulation and area computations. We then studied Stokes' theorem, which generalises Green's theorem to three dimensions, relating line integrals around curves to surface integrals of curl. Next, we examined the Divergence theorem (Gauss's theorem), which links surface integrals over closed surfaces to volume integrals of divergence, providing a powerful tool for flux and source analysis. Finally, we applied these theorems in practical contexts such as fluid dynamics, electromagnetism, and heat transfer, showing their indispensable role in science and engineering.

6. By completing this Series, you should now be able to define and apply Green's theorem in planar problems (SLO 4.1), demonstrate Stokes' theorem in three-dimensional contexts (SLO 4.2), evaluate the Divergence theorem and interpret its significance in flux and sources (SLO 4.3), and analyse the physical applications of these theorems in real-world scenarios (SLO 4.4). Together, these integral theorems unify line, surface, and volume integrals, forming the backbone of applied vector calculus.

Glossary of Terms

- Area integral: A double integral over a region in the plane, often connected to Green's theorem.

- Circulation: The line integral of a vector field around a closed curve, measuring rotational tendency.
- Curl: A vector operator that describes the rotation of a vector field, central to Stokes' theorem.
- Divergence: A scalar operator that measures the net outflow (sources or sinks) of a vector field, central to the Divergence theorem.
- Divergence theorem (Gauss's theorem): Relates a surface integral of a vector field over a closed surface to a volume integral of divergence.
- Flux: The amount of a vector field passing through a surface, measured by a surface integral.
- Green's theorem: Relates a line integral around a closed curve in the plane to a double integral over the region it encloses.
- Line integral: An integral taken along a curve, used to measure work, circulation, or accumulation along a path.
- Stokes' theorem: Relates a line integral around a closed curve to a surface integral of curl over the surface it bounds.
- Surface integral: An integral taken over a surface, used to measure flux or accumulation across a surface.
- Volume integral: An integral taken over a three-dimensional region, often used in the Divergence theorem.
- Vorticity: A measure of local rotation in a fluid, connected to curl and circulation.

Concept Check Questions 4

Objective questions

1. Green's theorem relates a line integral around a closed curve to: A. A surface integral B. A double integral over the region C. A volume integral D. None of the above (Linked to SLO 4.1)
2. Stokes' theorem relates a line integral around a closed curve to: A. A surface integral of curl B. A volume integral of divergence C. A scalar integral D. None of the above (Linked to SLO 4.2)

3. The Divergence theorem relates a surface integral over a closed surface to:
A. A line integral B. A volume integral of divergence C. A double integral
D. None of the above (Linked to SLO 4.3)
4. In electromagnetism, the Divergence theorem is central to: A. Ampère's law
B. Gauss's law C. Faraday's law D. None of the above (Linked to SLO 4.3)
5. Stokes' theorem is central to: A. Maxwell's equations B. Newton's laws C.
Fourier's law D. None of the above (Linked to SLO 4.2, 4.4)

Short-answer questions

6. State Green's theorem in words. (Linked to SLO 4.1)
7. Explain how Stokes' theorem generalises Green's theorem. (Linked to SLO 4.2)
8. What does divergence represent physically? (Linked to SLO 4.3)
9. Give one application of the Divergence theorem in electromagnetism.
(Linked to SLO 4.3)
10. How are integral theorems applied in fluid dynamics? (Linked to SLO 4.4)

Long-answer questions

11. Discuss the statement, interpretation, and applications of Green's theorem in planar problems. (Linked to SLO 4.1)
 - Basic response: State Green's theorem and explain its use in circulation and area integrals.
 - Value-added response: Provide detailed examples in fluid flow and geometry.
12. Analyse the role of Stokes' theorem in three-dimensional vector fields.
(Linked to SLO 4.2)
 - Basic response: State Stokes' theorem and explain its connection between line integrals and curl.
 - Value-added response: Extend to applications in electromagnetism and engineering.
13. Evaluate the significance of the Divergence theorem in flux and sources.
(Linked to SLO 4.3)
 - Basic response: State the Divergence theorem and explain its meaning.

- Value-added response: Discuss its role in Gauss's law, fluid dynamics, and heat transfer.

14. Examine the applied contexts of integral theorems in physics and engineering. (Linked to SLO 4.4)

- Basic response: Mention fluid dynamics, electromagnetism, and heat transfer.
- Value-added response: Provide detailed case studies showing how each theorem simplifies real-world problems.
- Answers to Pilot Questions 4
- Part 4.1 (Green's Theorem in the Plane) 1-B, 2-A, 3-B, 4-B, 5-B

Introduction

In this Series we turn our attention to the differential operators of vector calculus—gradient, divergence, and curl—and their role in analysing vector fields. These operators provide the local, pointwise information that complements the global relationships expressed by the integral theorems studied in Series 4.

The purpose of this Series is to help you understand how to compute and interpret these operators, and to see how they describe physical phenomena such as flow, rotation, and sources. We begin with the gradient of a scalar field, which points in the direction of greatest increase and measures the rate of change. Next, we study the divergence of a vector field, which quantifies sources and sinks, indicating how much a field spreads out from a point. We then examine the curl of a vector field, which measures rotation and vorticity. Finally, we explore applications of these operators in fluid dynamics, electromagnetism, and engineering, showing how they underpin the integral theorems and provide insight into real-world systems.

Series Learning Outcomes

Upon completing this Series, you should be able to:

- SLO 5.1 define and compute the gradient of a scalar field, and interpret its physical meaning in terms of direction and rate of change.
- SLO 5.2 evaluate the divergence of a vector field, and explain its significance in identifying sources and sinks.
- SLO 5.3 determine the curl of a vector field, and interpret its role in measuring rotation and vorticity.
- SLO 5.4 analyse the applications of gradient, divergence, and curl in fluid dynamics, electromagnetism, and engineering contexts.

5.1 Gradient of a Scalar Field

The gradient is a fundamental operator in vector calculus. It acts on a scalar field to produce a vector field that points in the direction of the greatest rate of increase of the scalar function.

Fill in the blank: The gradient of a scalar field points in the direction of greatest _____.

5.1.1 Definition of Gradient

For a scalar field $\phi(x,y,z)$, the gradient is defined as:

$$\nabla\phi$$

This vector points in the direction of maximum increase of ϕ , and its magnitude gives the rate of increase.

Gradient pointing in direction of maximum increase

5.1.2 Properties of Gradient

- Points in the direction of steepest ascent.
- Magnitude equals the rate of change in that direction.
- Perpendicular to level surfaces (contours) of the scalar field.

Fill in the blank: The gradient is always perpendicular to _____ surfaces of the scalar field.

5.1.3 Physical interpretation

- Temperature field: Gradient points toward the direction of greatest temperature increase.
- Potential field: Gradient represents the force in conservative fields (e.g., gravitational or electric potential).
- Topography: Gradient indicates slope direction and steepness on a terrain map.

Gradient applied to a temperature field

Fill in the blank: In a temperature field, the gradient points toward the direction of greatest _____ increase.

5.1.4 Worked example

Example: Find the gradient of $\phi(x,y,z)=x^2+y^2+z^2$.

Solution:

$$\begin{aligned}\nabla\phi &= (x(x^2+y^2+z^2), y(x^2+y^2+z^2), z(x^2+y^2+z^2)) \\ &= (2x, 2y, 2z)\end{aligned}$$

Thus, the gradient points radially outward from the origin, with magnitude proportional to the distance from the origin.

Fill in the blank: In the worked example, the gradient of $\phi(x,y,z)=x^2+y^2+z^2$ is _____.

Pilot questions 5.1

1. The gradient of a scalar field points in the direction of: A. Minimum value B. Maximum increase C. Zero change D. None of the above (Linked to SLO 5.1)
2. The formula for the gradient of $\phi(x,y,z)$ is: A. $\nabla\phi = z$ B. $\nabla\phi = z$ C. $\nabla\phi = z$ D. None of the above (Linked to SLO 5.1)
3. The gradient is always perpendicular to: A. Level surfaces B. Tangent lines C. Divergence D. None of the above (Linked to SLO 5.1)
4. In a temperature field, the gradient points toward the direction of greatest: A. Pressure increase B. Temperature increase C. Density increase D. None of the above (Linked to SLO 5.1)
5. For $\phi(x,y,z)=x^2+y^2+z^2$, the gradient is: A. $\nabla\phi = z$ B. $\nabla\phi = 2z$ C. $\nabla\phi = z^2$ D. None of the above (Linked to SLO 5.1)

5.2 Divergence of a Vector Field

The divergence is a differential operator that acts on a vector field to produce a scalar field. It measures the net rate at which the vector field “spreads out” from a point, indicating sources or sinks.

Fill in the blank: Divergence measures the net rate at which a vector field _____ from a point.

5.2.1 Definition of Divergence

For a vector field $F=(F_x,F_y,F_z)$, the divergence is defined as:

$$\text{Div } F = F_{xx} + F_{yy} + F_{zz}$$

This scalar quantity represents the density of sources or sinks at a given point.

Divergence representing sources in a vector field

5.2.2 Properties of Divergence

- Positive divergence indicates a source (field spreading outward).
- Negative divergence indicates a sink (field converging inward).
- Zero divergence indicates a solenoidal field (no net outflow or inflow).

Fill in the blank: A vector field with zero divergence is called a _____ field.

5.2.3 Physical interpretation

- Fluid dynamics: Divergence measures the net outflow of fluid from a point.
- Electromagnetism: Divergence of the electric field relates to charge density (Gauss's law).
- Heat transfer: Divergence of heat flux indicates sources or sinks of energy.

Divergence applied to fluid flow

Fill in the blank: In fluid dynamics, divergence measures the net _____ of fluid from a point.

5.2.4 Worked example

Example: Find the divergence of $F=(x,y,z)$.

Solution:

$$\text{Div } F = x(x) + y(y) + z(z) = 1 + 1 + 1 = 3$$

Thus, the divergence is constant and equal to 3 everywhere, indicating a uniform source density.

Fill in the blank: In the worked example, the divergence of $F=(x,y,z)$ is _____.

Pilot questions 5.2

1. Divergence measures the net rate at which a vector field: A. Rotates B. Spreads out C. Remains constant D. None of the above (Linked to SLO 5.2)
2. The formula for divergence of $F=(F_x, F_y, F_z)$ is: A. $F=F_{xx}+F_{yy}+F_{zz}$ B. $F \cdot C$ D. None of the above (Linked to SLO 5.2)
3. Positive divergence indicates: A. A sink B. A source C. Zero flow D. None of the above (Linked to SLO 5.2)
4. In fluid dynamics, divergence measures the net: A. Rotation of fluid B. Outflow of fluid C. Gradient of fluid D. None of the above (Linked to SLO 5.2)
5. For $F=(x,y,z)$, the divergence is: A. 1 B. 2 C. 3 D. None of the above (Linked to SLO 5.2)

5.3 Curl of a Vector Field

The curl is a differential operator that acts on a vector field to produce another vector field. It measures the tendency of the field to rotate around a point, capturing local rotational effects.

Fill in the blank: Curl measures the tendency of a vector field to _____ around a point.

5.3.1 Definition of Curl

For a vector field $F=(F_x, F_y, F_z)$, the curl is defined as:

$$\nabla \times F = (F_{zy} - F_{yz}, F_{xz} - F_{zx}, F_{yx} - F_{xy})$$

This vector represents the axis and magnitude of rotation at each point in the field.

Curl representing rotation in a vector field

5.3.2 Properties of Curl

- Curl is a vector quantity.
- Direction of curl indicates the axis of rotation.
- Magnitude of curl indicates the strength of rotation.

- A field with zero curl is called irrotational.

Fill in the blank: A vector field with zero curl is called an _____ field.

5.3.3 Physical interpretation

- Fluid dynamics: Curl measures vorticity, indicating local spinning motion of fluid.
- Electromagnetism: Curl of the electric field relates to changing magnetic fields (Faraday's law).
- Engineering: Curl is used in stress and strain analysis to model rotational effects.

Curl applied to fluid vorticity

Fill in the blank: In fluid dynamics, curl measures _____, indicating local spinning motion of fluid.

5.3.4 Worked example

Example: Find the curl of $F=(-y,x,0)$.

Solution:

$$\begin{aligned} F &= 0y - xz, (-y)z - 0x, xx - (-y)y \\ &= (0 - 0, 0 - 0, 1 - (-1)) = (0, 0, 2) \end{aligned}$$

Thus, the curl is 2, pointing along the z-axis, indicating rotation around the vertical axis.

Fill in the blank: In the worked example, the curl of $F=(-y,x,0)$ is _____.

Pilot questions 5.3

1. Curl measures the tendency of a vector field to: A. Spread out B. Rotate C. Remain constant D. None of the above (Linked to SLO 5.3)
2. The formula for curl of $F=(F_x,F_y,F_z)$ is: A. F_B . C. F_D . None of the above (Linked to SLO 5.3)
3. A vector field with zero curl is called: A. Solenoidal B. Irrotational C. Divergent D. None of the above (Linked to SLO 5.3)

4. In fluid dynamics, curl measures: A. Gradient B. Vorticity C. Divergence D. None of the above (Linked to SLO 5.3)
5. For $F=(-y,x,0)$, the curl is: A. 1 B. 2 C. 0 D. None of the above (Linked to SLO 5.3)

5.4 Applications of Gradient, Divergence, and Curl

The three differential operators—gradient, divergence, and curl—are the backbone of vector calculus applications in physics and engineering. They describe local behaviours of fields and connect directly to physical laws.

Fill in the blank: Gradient, divergence, and curl are the backbone of _____ calculus applications in physics and engineering.

5.4.1 Fluid dynamics

- Gradient: Describes pressure or velocity changes in fluid flow.
- Divergence: Measures net outflow of fluid, indicating sources or sinks.
- Curl: Represents vorticity, showing rotational behaviour of fluid particles.

Applications of differential operators in fluid dynamics

5.4.2 Electromagnetism

- Gradient: Electric potential gradient gives the electric field.
- Divergence: Divergence of electric field relates to charge density (Gauss's law).
- Curl: Curl of electric and magnetic fields connects to Maxwell's equations (Faraday's and Ampère's laws).

Applications of differential operators in electromagnetism

Fill in the blank: In electromagnetism, the gradient of electric potential gives the _____ field.

5.4.3 Engineering and applied sciences

- Gradient: Used in stress analysis and optimisation problems.
- Divergence: Applied in heat transfer to model energy flow and sources.
- Curl: Used in mechanical engineering to analyse rotational stresses.

Applications of differential operators in engineering

Fill in the blank: In heat transfer, divergence is used to model _____ flow and sources inside a region.

Pilot questions 5.4

1. Gradient, divergence, and curl are the backbone of: A. Algebra B. Vector calculus C. Geometry D. None of the above (Linked to SLO 5.4)
2. In fluid dynamics, curl represents: A. Divergence B. Vorticity C. Gradient D. None of the above (Linked to SLO 5.4)
3. In electromagnetism, the gradient of electric potential gives the: A. Magnetic field B. Electric field C. Heat field D. None of the above (Linked to SLO 5.4)
4. Divergence of the electric field relates to: A. Charge density B. Current density C. Temperature D. None of the above (Linked to SLO 5.4)
5. In heat transfer, divergence is used to model: A. Energy flow and sources B. Circulation C. Gradient D. None of the above (Linked to SLO 5.4)

Series Summary

This Series has focused on the differential operators of vector calculus—gradient, divergence, and curl—and their applications. We began with the gradient of a scalar field, which points in the direction of greatest increase and measures the rate of change. Next, we studied the divergence of a vector field, which quantifies sources and sinks, indicating how much a field spreads out from a point. We then examined the curl of a vector field, which measures rotation and vorticity, capturing local spinning behaviour. Finally, we explored how these operators are applied in fluid dynamics, electromagnetism, and engineering, showing their indispensable role in modelling flows, fields, and stresses.

By completing this Series, you should now be able to compute and interpret the gradient (SLO 5.1), evaluate divergence and explain its physical meaning (SLO 5.2), determine curl and connect it to rotation and vorticity (SLO 5.3), and analyse how these operators apply in real-world contexts (SLO 5.4). Together, gradient, divergence, and curl provide the local tools

that underpin the global integral theorems studied previously, forming a complete framework for vector calculus in applied sciences.

Glossary of Terms – Series 5

- **Gradient:** A vector operator acting on a scalar field, pointing in the direction of greatest increase and measuring the rate of change.
- **Level surface (contour):** A surface where a scalar field has a constant value; the gradient is always perpendicular to it.
- **Divergence:** A scalar operator acting on a vector field, measuring the net outflow (sources or sinks) from a point.
- **Source:** A point where a vector field spreads outward, indicated by positive divergence.
- **Sink:** A point where a vector field converges inward, indicated by negative divergence.
- **Solenoidal field:** A vector field with zero divergence, meaning no net outflow or inflow.
- **Curl:** A vector operator acting on a vector field, measuring local rotation or vorticity.
- **Irrotational field:** A vector field with zero curl, meaning no local rotation.
- **Vorticity:** A measure of local spinning motion in fluid dynamics, represented by curl.
- **Flux:** The amount of a vector field passing through a surface, often linked to divergence.
- **Potential field:** A scalar field whose gradient represents a force, such as gravitational or electric potential

Concept Check Questions 5

Objective questions

1. The gradient of a scalar field points in the direction of: A. Minimum value B. Maximum increase C. Zero change D. None of the above (Linked to SLO 5.1)
2. Divergence measures the net rate at which a vector field: A. Rotates B. Spreads out C. Remains constant D. None of the above (Linked to SLO 5.2)
3. Curl measures the tendency of a vector field to: A. Spread out B. Rotate C. Stay uniform D. None of the above (Linked to SLO 5.3)
4. In electromagnetism, the gradient of electric potential gives the: A. Magnetic field B. Electric field C. Heat field D. None of the above (Linked to SLO 5.4)

5. In fluid dynamics, curl represents: A. Divergence B. Vorticity C. Gradient
D. None of the above (Linked to SLO 5.4)

Short-answer questions

6. Define the gradient of a scalar field and explain its physical meaning.
(Linked to SLO 5.1)
7. What does divergence represent physically in a vector field? (Linked to SLO 5.2)
8. Explain the difference between a solenoidal field and an irrotational field.
(Linked to SLO 5.2, 5.3)
9. Give one application of curl in fluid dynamics. (Linked to SLO 5.3)
10. How are gradient, divergence, and curl applied in electromagnetism?
(Linked to SLO 5.4)

Long-answer questions

11. Discuss the definition, properties, and applications of the gradient of a scalar field. (Linked to SLO 5.1)
- Basic response: Define gradient and explain its direction and magnitude.
 - Value-added response: Provide examples in temperature fields and potential fields.
12. Analyse the role of divergence in vector fields. (Linked to SLO 5.2)
- Basic response: Define divergence and explain sources and sinks.
 - Value-added response: Extend to applications in fluid dynamics and electromagnetism.
13. Evaluate the significance of curl in measuring rotation and vorticity. (Linked to SLO 5.3)
- Basic response: Define curl and explain its meaning.
 - Value-added response: Discuss its role in fluid dynamics and Maxwell's equations.
14. Examine the applied contexts of gradient, divergence, and curl in physics and engineering. (Linked to SLO 5.4)
- Basic response: Mention fluid dynamics, electromagnetism, and heat transfer.
 - Value-added response

Answers to Pilot Questions 5

Part 5.1 (Gradient of a Scalar Field) 1-B, 2-A, 3-A, 4-B, 5-B

Part 5.2 (Divergence of a Vector Field) 1-B, 2-A, 3-B, 4-B, 5-C

Part 5.3 (Curl of a Vector Field) 1-B, 2-C, 3-B, 4-B, 5-B

Part 5.4 (Applications of Gradient, Divergence, and Curl) 1-B, 2-B, 3-B, 4-A, 5-A
